Different Basins Different Approaches

(a) Marcellus Shale,
Susquehanna River Basin

4.1-4.6 million gallons
injected

420,000-1.3 million gallons
produced

■ Reuse in hydraulic fracturing
■ Class II well

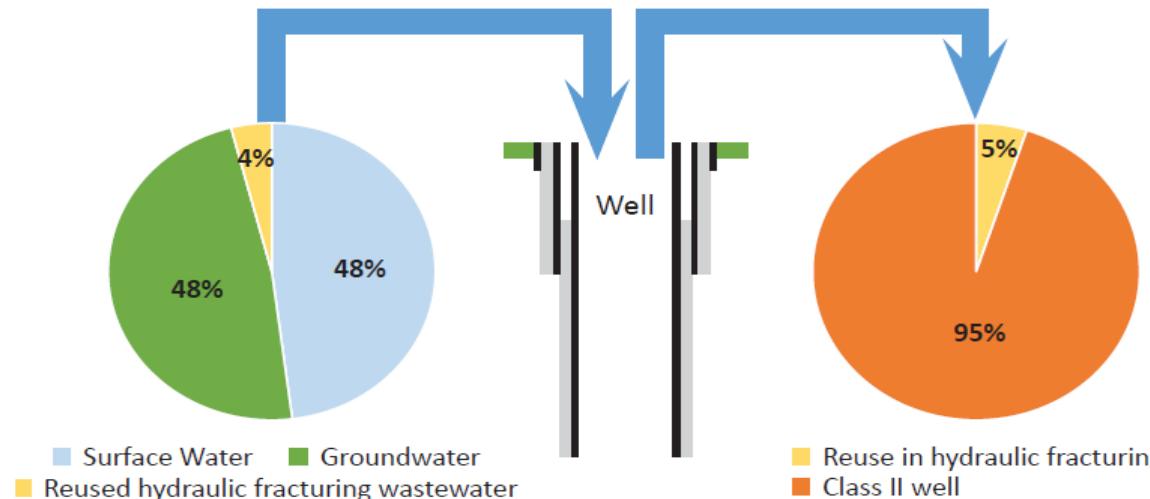

*Less than approximately 1% is treated at facilities that are either permitted to discharge to surface water or whose discharge status is uncertain.

Most of the injected fluid stays in the subsurface; produced water volumes over 10 years are approximately 10-30% of the injected fluid volume.

(b) Barnett Shale, Texas

3.9-4.5 million gallons
injected

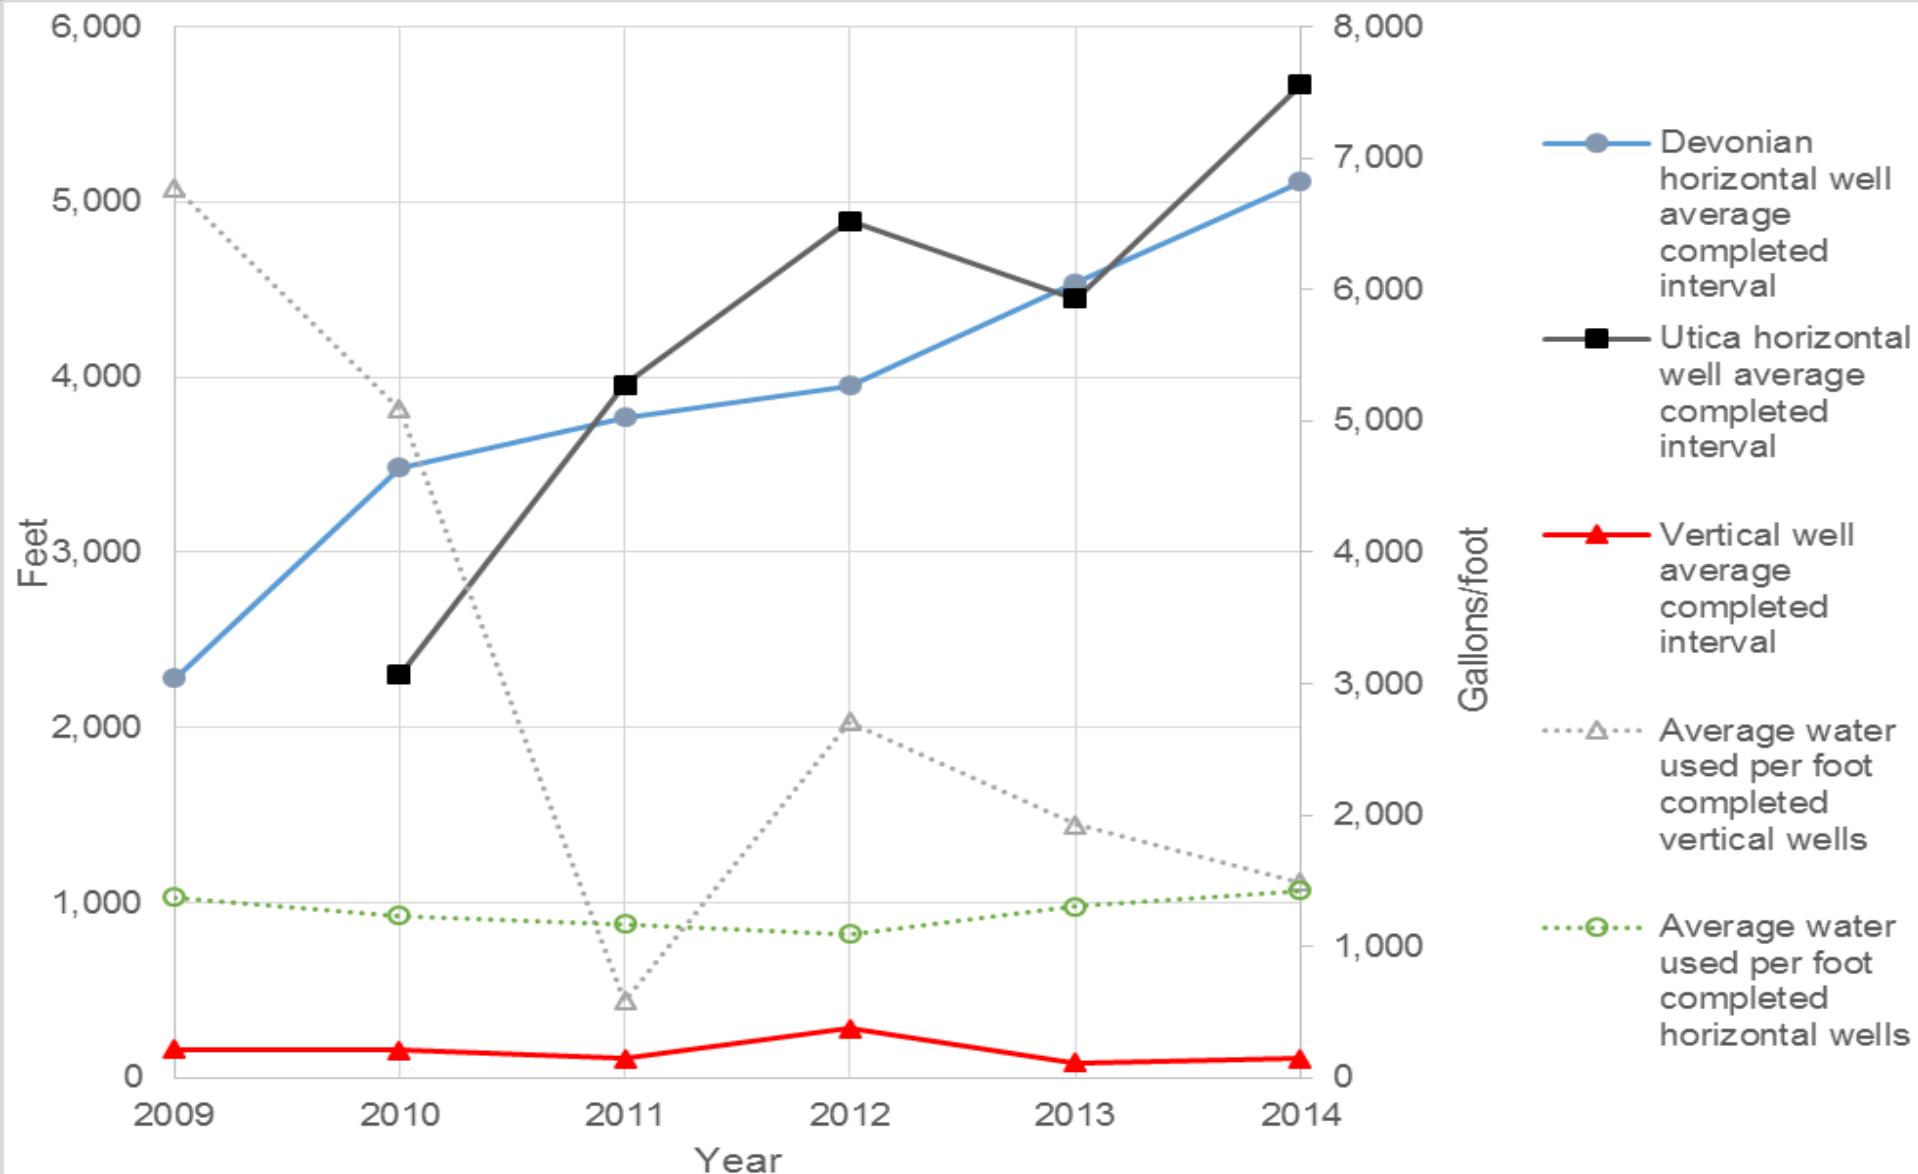

3.9-4.5 million gallons
produced

■ Reuse in hydraulic fracturing
■ Class II well

Produced water volumes over three years can be approximately the same as the injected fluid volume.

Well length vs Water use per foot in PA

Flowback and Produced Fluids Management

~5% of injected fluids return initially as flowback depending on formation

5 BBLs of fluids produced with every 1 MMCF of gas during the productive life of a well

Recycling/reuse rate of 92% in PA in 2016

Fluids management options

- Direct reuse (blending)
- On-site treatment w/reuse
- Off-site treatment w/reuse
- Treatment with discharge
- Class II UIC well disposal

Treatment technologies

- Filtration (sock filters)
- Chemical precipitation
- Evaporation (eg MVR)
- Crystallization

PennState

MCOR

Marcellus Center for Outreach and Research

Field Treatment Technologies

Field treatment for recycling benefits:

- Cost effective
- Improving technology and efficiency
- Less trucking transport
- Lower visibility
- Minimize fresh water use
- Less overall environmental impact
- In PA in 2016 about 60% of fluids that were recycled were managed in the field

Relative Volumes of Frac Water Used in PA

PA Class IID UIC Well Locations

- 6 operational Class IID UIC wells in PA w/ 3 permitted but offline and ~5 permits in review
- 60,000 BPM of commercial capacity via two Class IID wells in PA
- Most wells targeting depleted sandstone gas reservoirs (Oriskany, Medina, Elk Sands)
- Nearly 95% of PA unconventional brine disposed of via OH wells

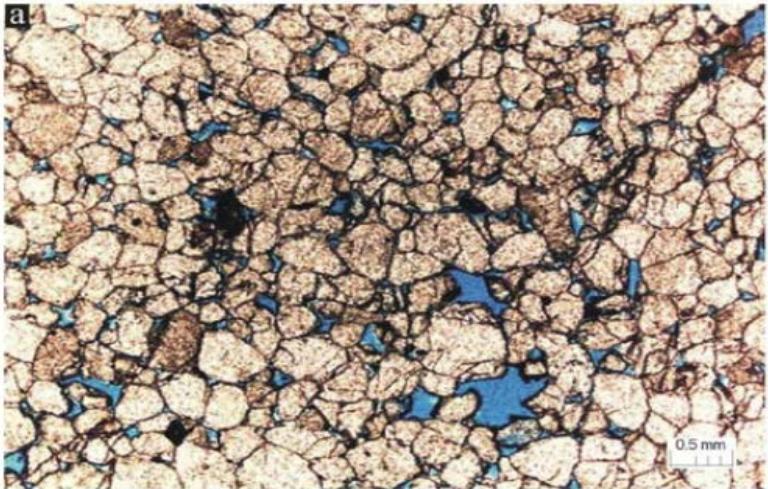

PennState

MCOR

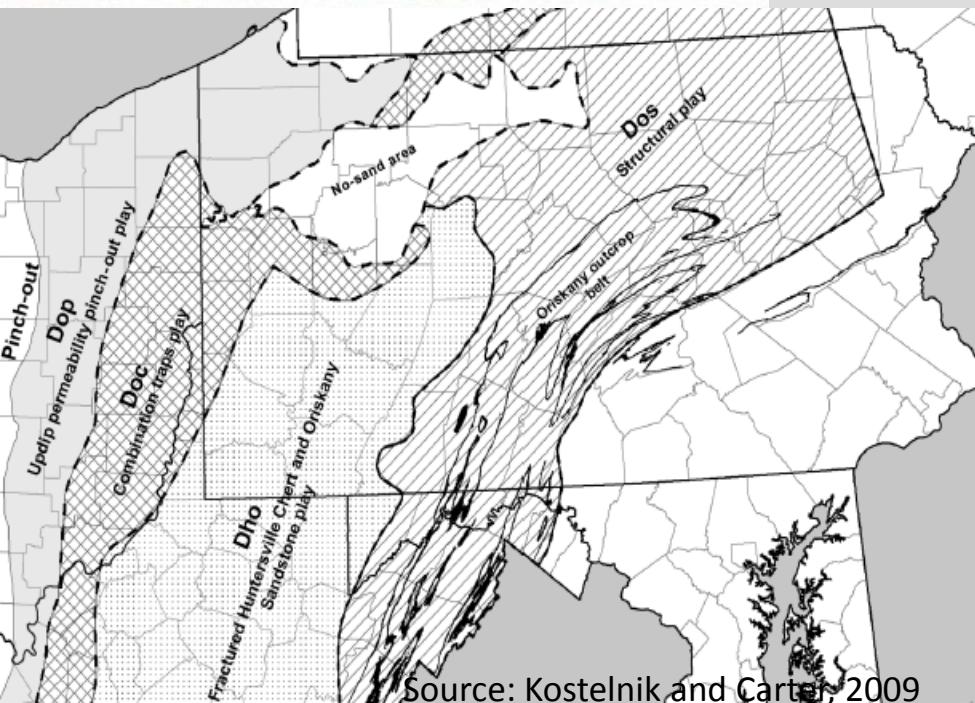

Marcellus Center for Outreach and Research

Example of Injection Capacity-Oriskany Sandstone

Oriskany sandstone

- calcite-cemented quartzite to chert with variable primary and fracture porosity
- depleted conventional gas reservoir
- used for brine injection and gas storage

Estimated Brine Injection Capacity (Volumetric)

- Using effective porosity of 4%, 50 feet of pay, and 40-ac injection zone area
- A typical injection well in the depleted Oriskany sandstone could ultimately accommodate an estimated 620,000 BBLs (~26 million gallons) of brine before filling available porosity
- Need to determine reservoir frac pressure to determine actual upper limit of injection

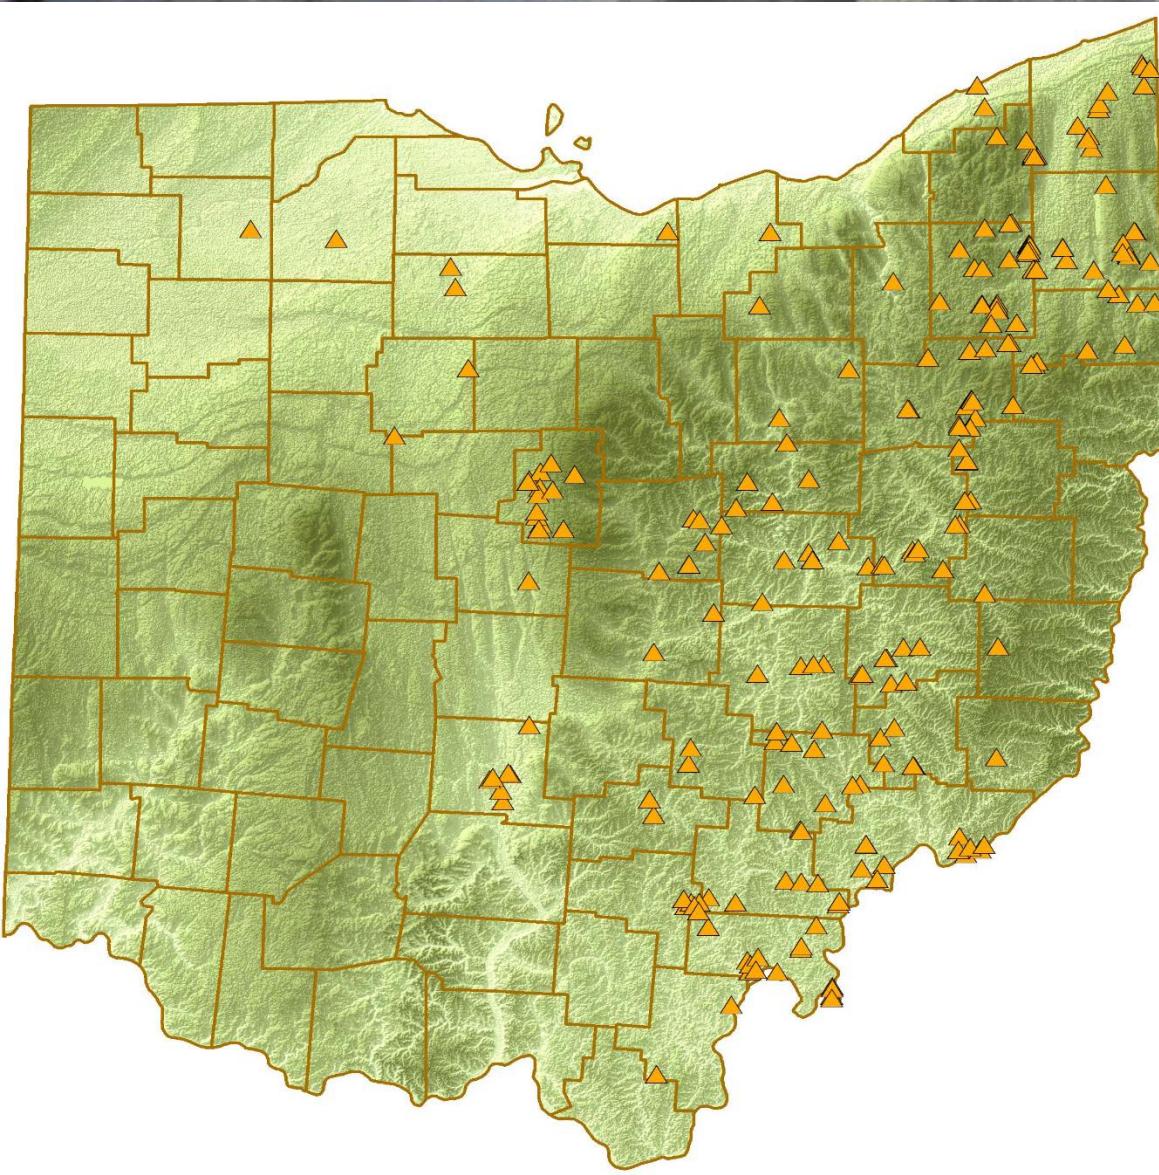

PennState

MCOR

Marcellus Center for Outreach and Research

Class IID UIC Wells in Ohio

- 217 operational Class IID wells in OH
- Estimated 30 MMBBLs injected in 2016
- Approximately 43% of injected fluids from out of state
- Average injection rate of 400 BPD/well

Marcellus Shale Energy and Brine Production

Current Production

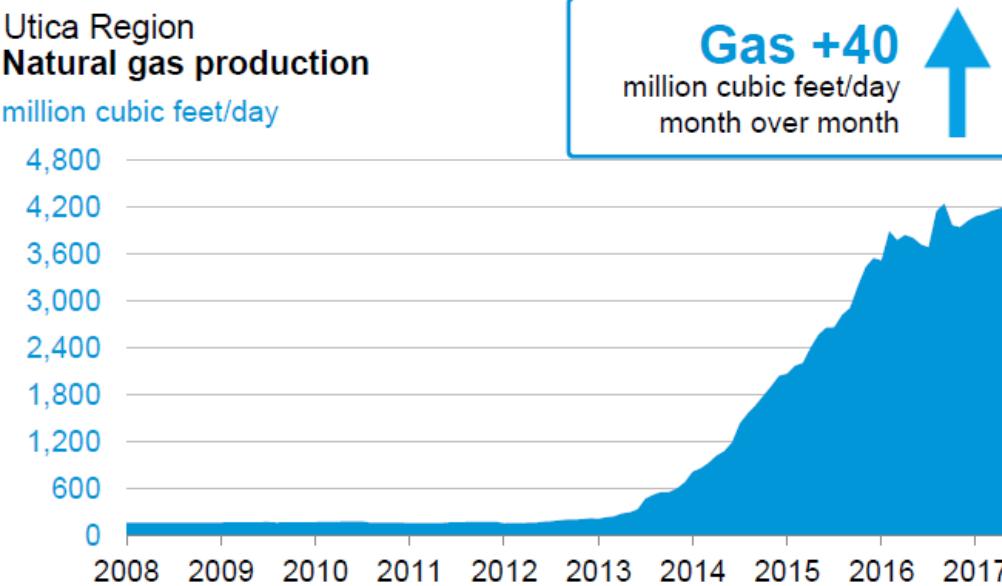

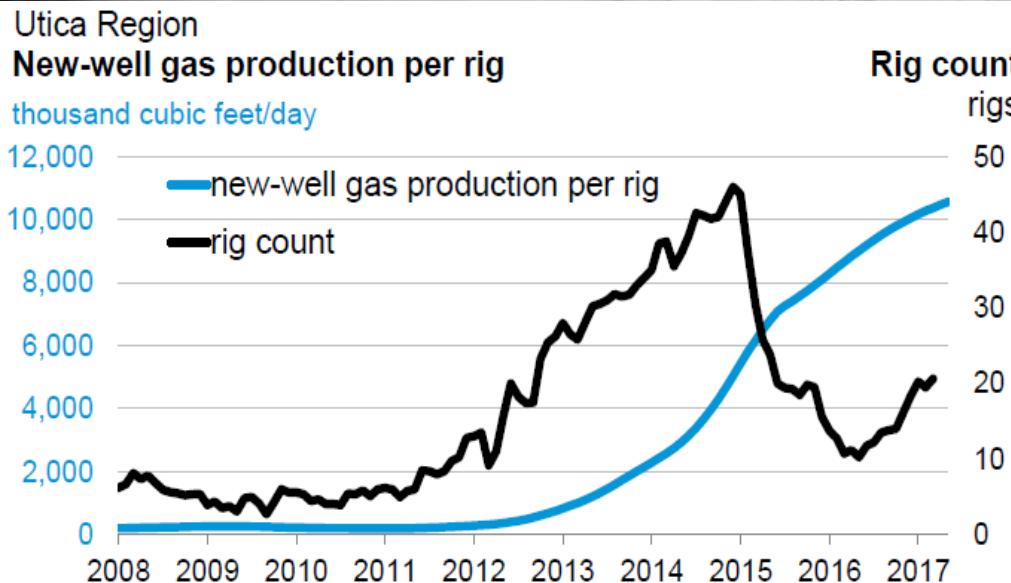

- 19 BCF/D of gas
- 3800 BBLs/D of oil
- 5 BBLs of brine/MMCF gas
- Current estimate of 95,000 BBLs/D of produced fluids
- 24.2 MMBBLs of fluids in PA in 2016
 - 3.5 MMBBLs of flowback
 - 20.7 MMBBLs of produced fluids
- In PA 92% recycled and <1% treated for discharge, with 8% disposal via Class IID wells (2016)

Utica/Pt. Pleasant Shale Energy and Brine Production

Current Production

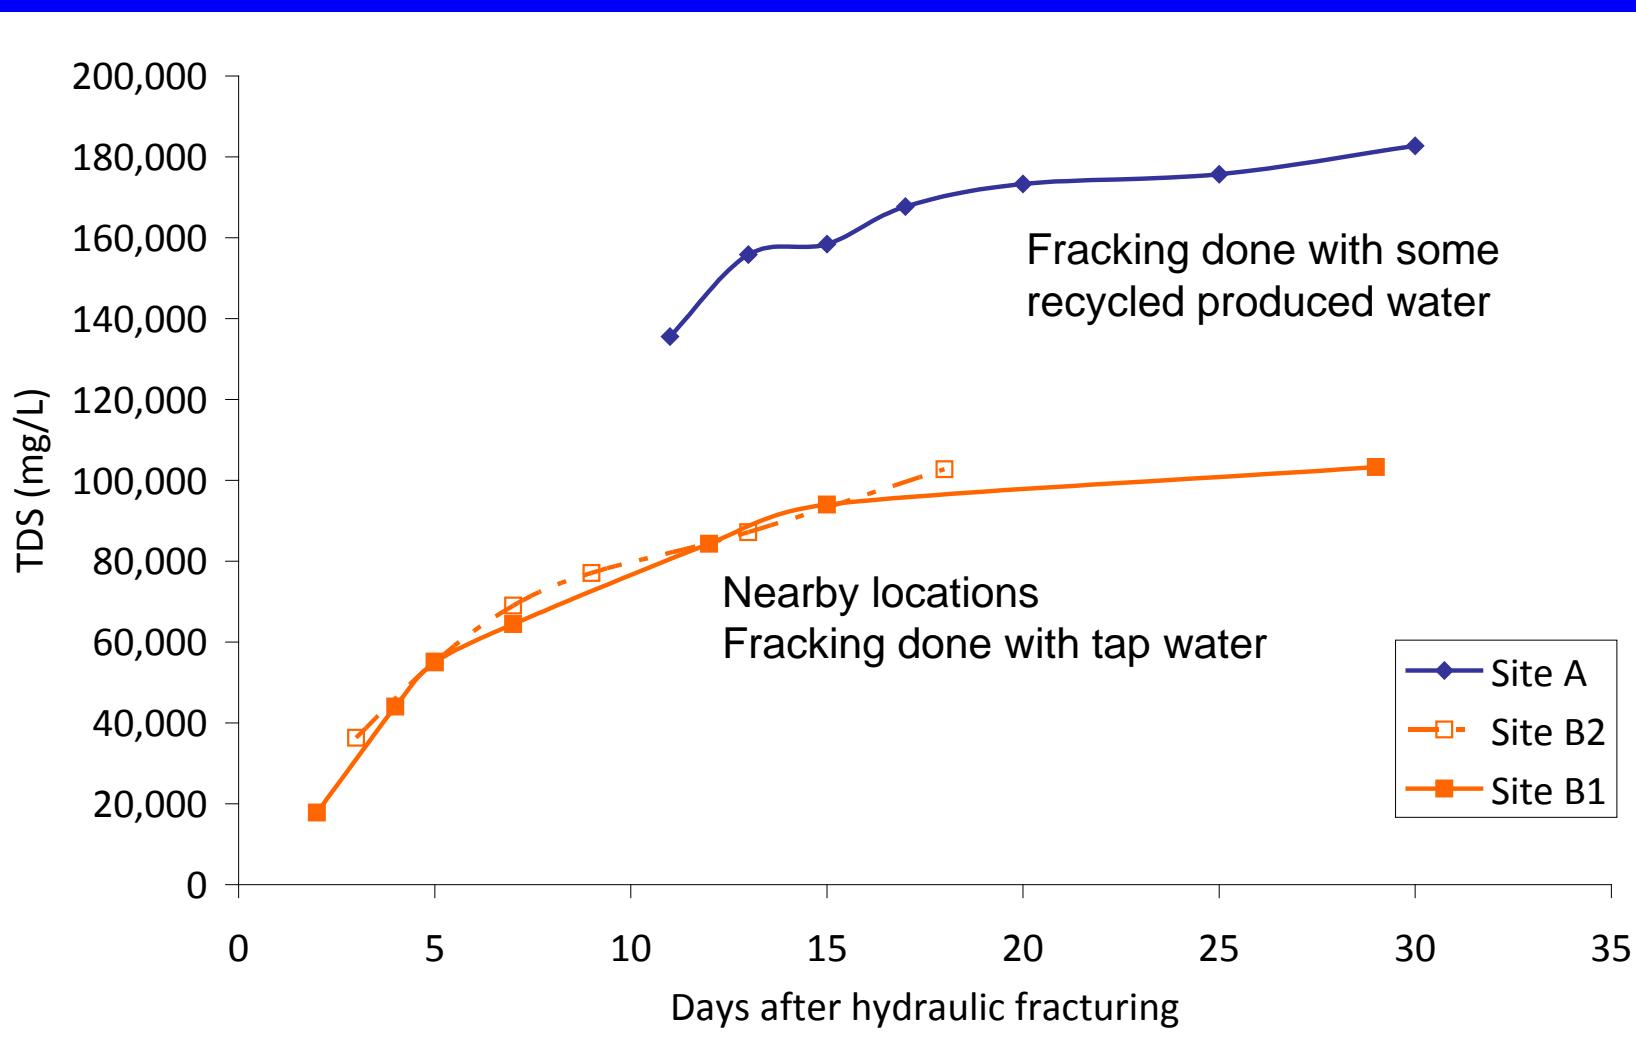

- 4.2 BCF/D of gas
- 39 MBBLs/D of oil
- Current estimate of 50,000 BBLs/D of produced fluids (assuming 12.5 BBLs brine per MMCF gas)

Flowback Water Quality

Constituent	Low	Medium	High
Ba (mg/L)	2,300	3,310	13,500
Sr (mg/L)	1,390	2,100	8,460
Ca (mg/L)	5,140	14,100	41,000
Mg (mg/L)	438	938	2,550
Hardness (mg /L as CaCO ₃)	17,900	49,400	90,337
TDS (mg/L)	69,400	175,600	345,000
Gross Beta (pCi/L)	ND	43,415	597,000
Ra ²²⁶ (pCi/L)	ND	623	9,280
COD (mg/L)	850	12,550	36,600

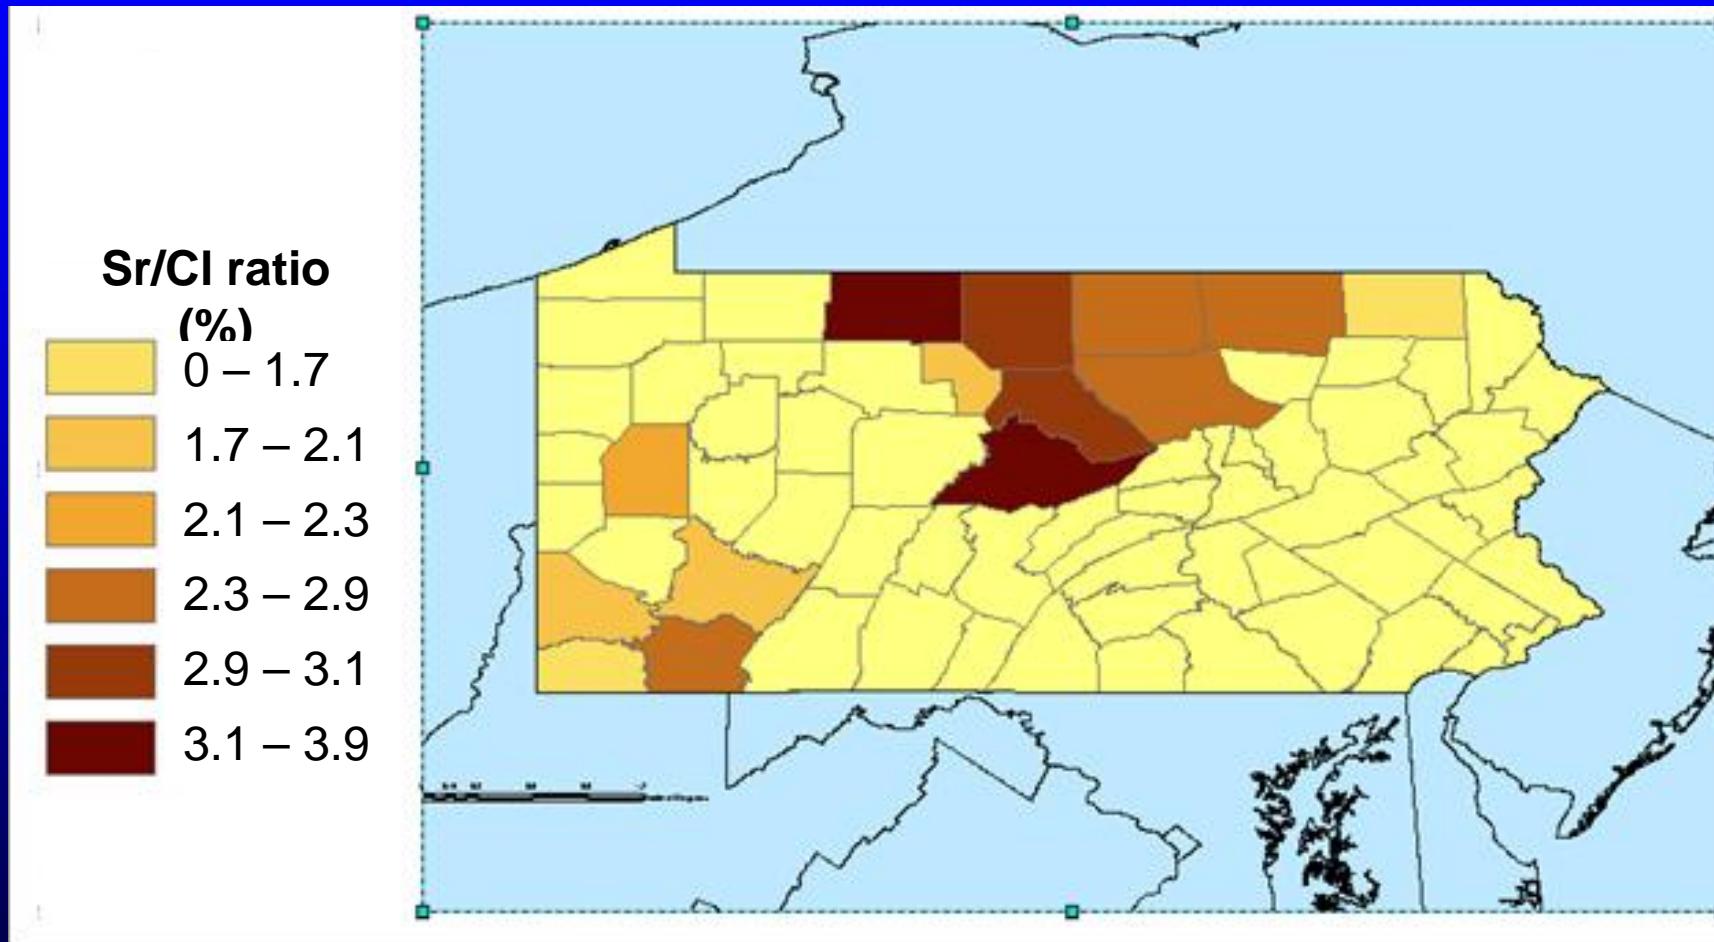

Flowback Water Quality: Ba trends

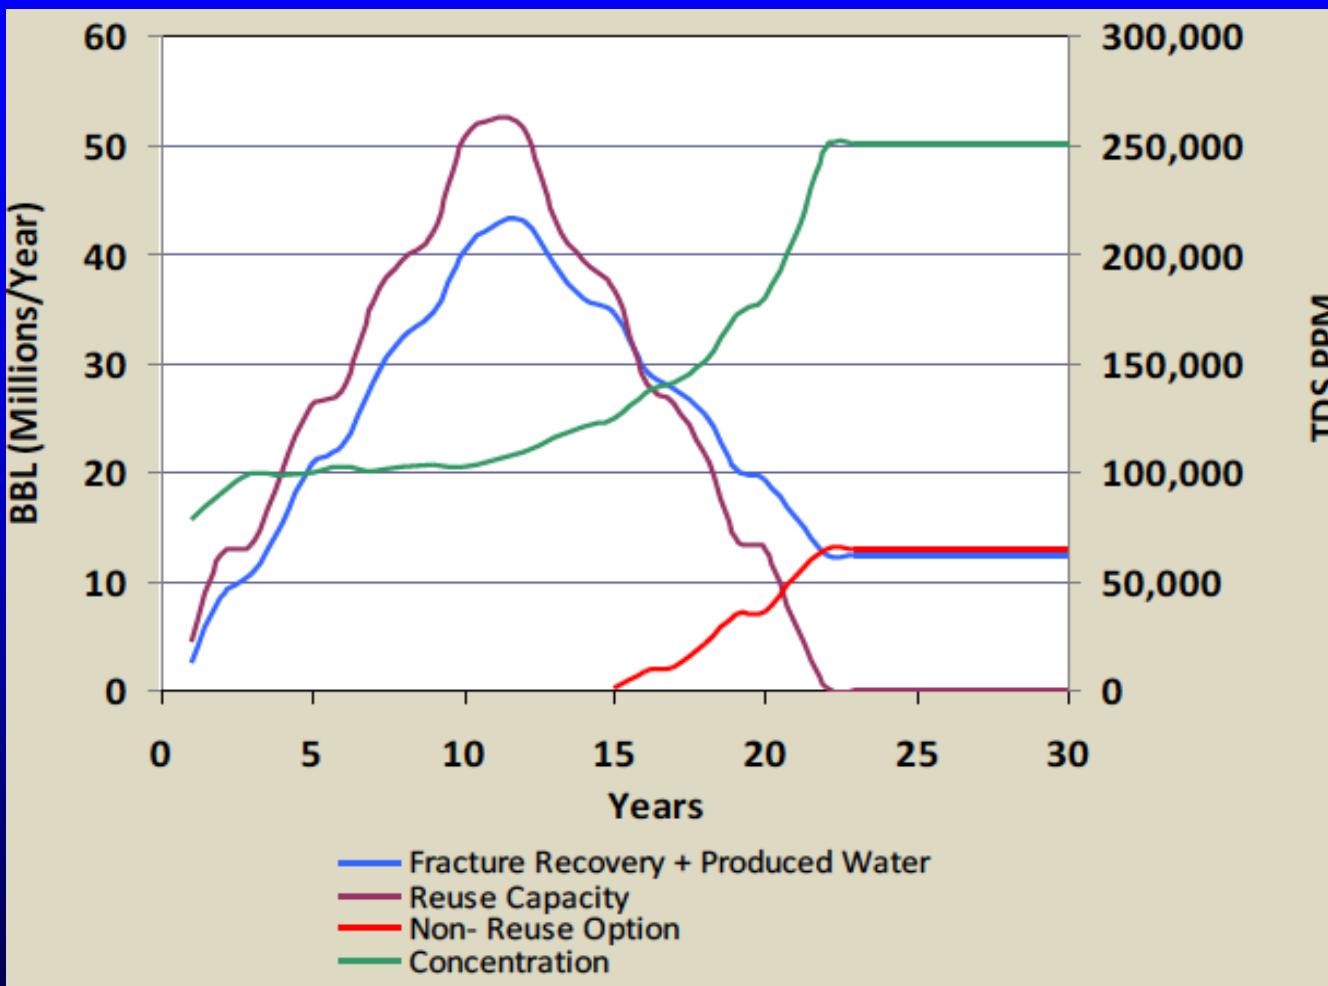

Barbot, et al., ES&T, 47, 2562-2569, 2013

Flowback Water Quality: Sr trends

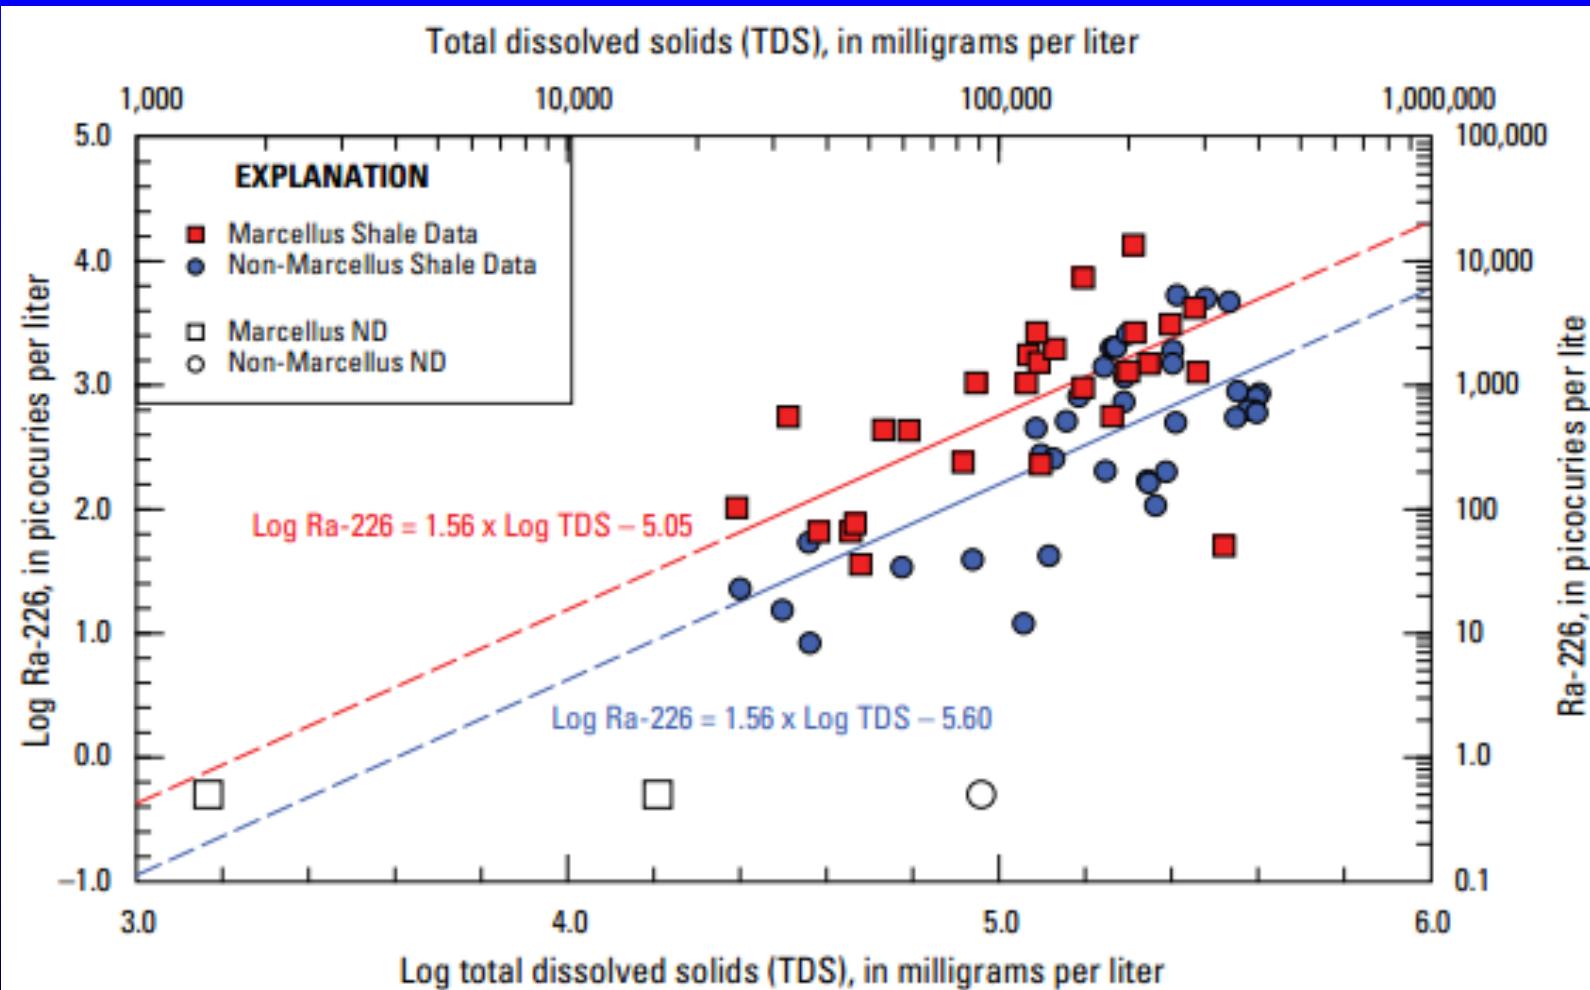

Recycling/Reuse

- Recycling works for 12-15 yr with a continuous increase in salinity
- Eventually net water production in a field

Radium in Flowback Water

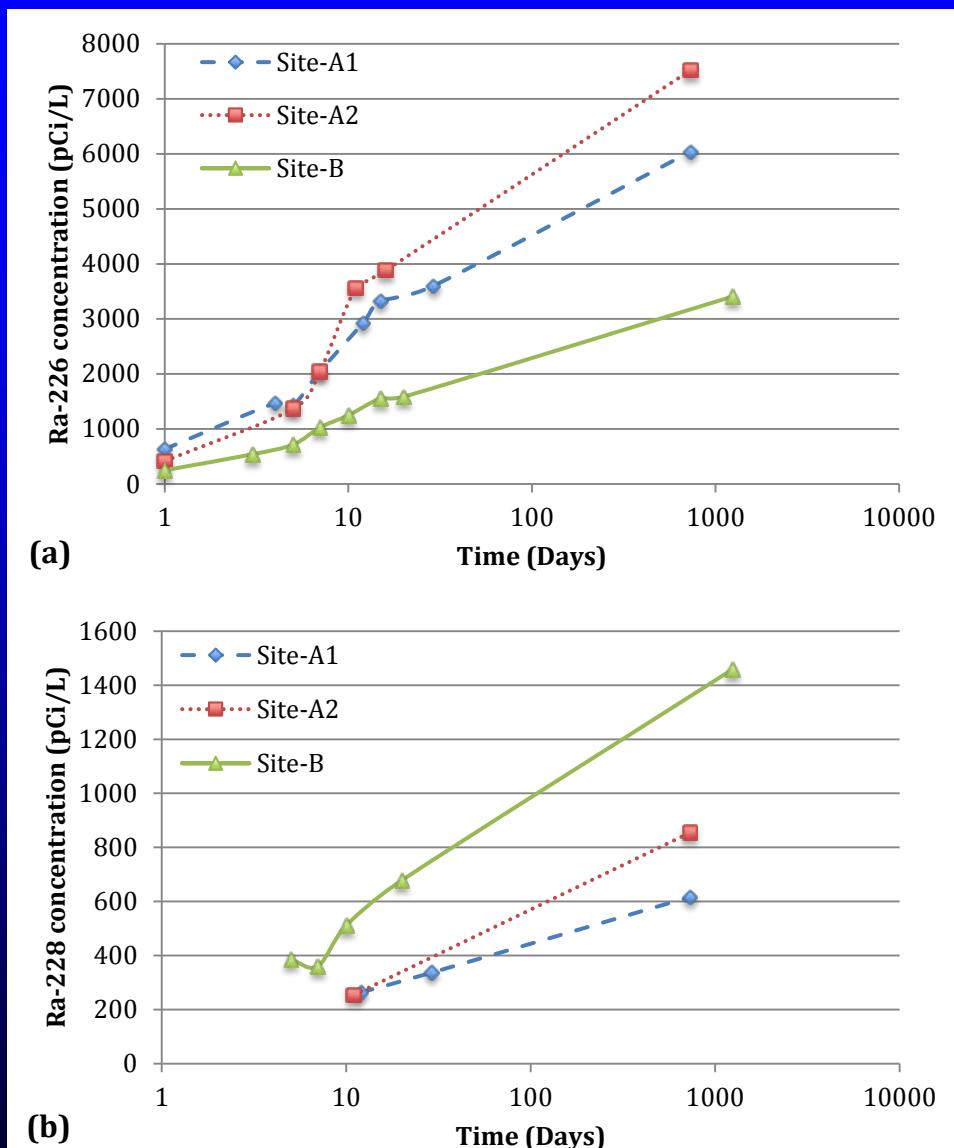

USGS, 2011.

Fate of Radium in Marcellus flowback water

- Ra-226/228 keeps increasing after the hydraulic-fracturing is completed;
- Ra concentration is highly depend on the local lithology of the shale;
- Ra-226 concentration ranges from several hundred to several thousand pCi/L.

Radioactive solid waste accumulation in storage impoundments

<p>Ra226: Liquid: 1410 pCi/L; Sludge: 8.8 pCi/g</p> <p>Impoundment A</p>	<p>Sampled in late 2010</p>	<p>Ra226: Liquid: 0 pCi/L; No sludge.</p> <p>Impoundment B</p>
<p>Ra226: Liquid: 2510 pCi/L; Sludge: 872 pCi/g</p> <p>Impoundment A</p>	<p>Sampled in early 2013</p>	<p>Ra226: Liquid: 1470 pCi/L; Sludge: 121 pCi/g</p> <p>Impoundment B</p>

- Ra keeps accumulating in the bottom sludge of storage impoundments
- Ra concentration ranges from <10 to several hundred pCi/g, which exceeds regulatory limit for landfill disposal (25 pCi/g).

Zhang et al. ES&T, 49, 9347-9354, 2015.

Summary

- Chemical reactions influence the quality of the early flowback water but the salinity of produced water continues to increase ($\sim 300,000$ mg/L)
- Produced water quality depends on local lithology (NE vs. SW)
- Recycling of produced water is not limited by its quality but it leads to an overall increase in the salinity of water in a well field
- NORM concentration in produced water increases with time and NORM accumulates in storage reservoirs
